# Agradecimentos

# Resumo

Este trabalho estuda estratégias de otimização para o problema de empacotamento de itens retangulares, com o uso da técnica bottom-left. A escolha dessa técnica se deve a dificuldade de usar métodos exatos para resolução em tempo hábil. Algoritmos serão implementados e instâncias de teste serão escolhidas para fins comparativos com os resultados de outros autores.

Palavras-chave: problema de empacotamento, otimização, heurística, pesquisa operacional.

# **Abstract**

This work studies optimization strategies for the packing problem of rectangular items, using the bottom-left technique. The choice of this technique is due to the difficulty of using exact methods for timely resolution. Algorithms will be implemented and test instances will be chosen for comparative purposes with the results of other authors.

Keywords: packing problem, optimization, heuristic, operational research.

# Introdução

Este trabalho visa estudar o Problema de Empacotamento de peças retangulares em uma caixa também retangular no espaço de duas dimensões, sendo sua solução considerada NP-difícil (IORI; LIMA et al., 2022). Antes de abordar o problema (Capítulo 2) e buscar soluções alguns conceitos básicos são mostrados no Capítulo 1.

O Capítulo 1 foca em definições sobre otimização (seção 1.2) e em modelos de otimização (seção 1.1 e seção 1.3). No Capítulo 2 é dada a definição do problema (seção 2.1), para então mostrar algumas classificações (seção 2.2) e variantes (seção 2.3), por fim é explicada a heurística bottom-left (Capítulo 3), a qual será utilizada na resolução das instâncias de teste.

O problema tem várias aplicações nas indústrias de móveis, têxtil e metal-mecânica (QUEIROZ, 2022; CAVALI, 2004; BELLUZZO; MORABITO, 2005), além ser extremamente útil em carregamento de paletes e *containers* (MORABITO NETO; WIDMER, 1992). É possível dividir o problema de acordo com sua dimensão.

Problemas unidimensionais podem ser associados ao corte de barras ou canos, para atender uma demanda por peças de diferentes tamanhos. As indústrias de tecido ou couro usam o caso 2D para minimizar o desperdício ao se cortar suas peças. O caso 3D é facilmente associável ao carregamento de *containers*, onde objetos são geralmente caixas a serem alocadas em algum veículo. A Figura 1 mostra um exemplo para cada dimensão do problema.

Basicamente, pode-se aplicá-lo em qualquer área que precise de organização ou logística, bem como situações que envolvam o corte de algum material. Ao utilizar soluções para resolver problemas de empacotamento, é possível reduzir o desperdício de materiais e impacto ambiental, diminuir tempo de entregas e otimizar espaços de estoque.

Introdução 10

# Objetivos

O principal objetivo deste trabalho é estudar e compreender o problema de empacotamento bem como suas aplicações no mundo real. Outros objetivos mais específicos são: revisar a bibliografia, implementar heurísticas baseadas em *bottom-left*, definir instâncias de teste e analisar os dados obtidos e compará-los com os de outros autores.

# 1 Conceitos Básicos

Antes de estudar o problema, são necessários alguns conceitos básicos e definição formal de termos importantes para a área de Pesquisa Operacional e otimização. Pesquisa Operacional pode ser entendida como o estudo e a aplicação de métodos científicos para tomada de decisões em problemas complexos (ARENALES et al., 2007, p.IX). Ela permite modelar, analisar e solucionar tais problemas de modo, geralmente, satisfatório.

Neste capítulo será explicado sobre modelos de otimização (seção 1.1) e seus tipos (seção 1.3), além de algumas definições sobre otimização (seção 1.2), finalizando com a diferença entre métodos heurísticos e exatos (seção 1.4). O problema de empacotamento de retângulos (detalhado no Capítulo 2), alvo deste estudo, é determinístico e pode ser modelado utilizando programação linear inteira mista (WOLSEY, 2020). No trabalho, o problema será explorado do ponto de vista heurístico, com o método apresentado no Capítulo 3.

# 1.1 Modelos de Otimização

Modelos são aproximações da realidade, representam o problema de maneira simples e objetiva, usando restrições. Eles são o que baseiam a Pesquisa Operacional. De forma geral, um modelo de otimização quer minimizar ou maximizar uma função f(x) com x obedecendo algumas restrições. Pode-se então representar o modelo do seguinte modo:

$$\min/\max f(x), x \in \mathcal{X}.$$

Onde

- x: variável de decisão,  $x = x_1, x_2, \ldots, x_n$ .
- $\bullet$   $\mathcal{X}$ : conjunto factível ou domínio, possui todas as soluções possíveis para o problema.
- f(x): função objetivo, a qual determinará o critério de escolha da solução.

Usando o problema da mochila como exemplo, onde se busca maximizar o valor dos itens alocados sem que seus pesos ultrapassem a capacidade da mochila (IORI; DE LIMA et al., 2021), um modelo possível é:

$$\max \sum_{i \in I} v_i x_i : \sum_{i \in I} w_i x_i \le C$$

Em que I é um conjunto de itens,  $v_i$  e  $w_i$  são, respectivamente o valor e o peso do item  $i \in I$ , C é a capacidade da mochila e  $x_i$  são variáveis binárias indicando se o item foi escolhido para mochila ou não.

## 1.2 Definições

A seguir serão dadas as definições de quatro expressões que aparecem com frequência no estudo de problemas de otimização.

Uma solução x' é **factível** somente se satisfaz todas as restrições dadas ao problema, ou seja,  $x' \in \mathcal{X}$ . Existem casos onde o problema não tem solução, possivelmente por muitas restrições terem sido aplicadas. Isso é chamado **problema infactível** e  $\mathcal{X} = \emptyset$ . Se para toda solução for possível encontrar outra melhor o problema é dito **ilimitado**.

Uma solução x' é **ótima** somente se for **factível** e possuir resultado melhor que as demais soluções, isto é,  $f(x') \leq f(x), \forall x \in \mathcal{X}$  (caso seja um problema de maximização é necessário substituir " $\leq$ " por " $\geq$ "). Importante observar que existe somente solução ótima se o problema não for infactível nem ilimitado.

# 1.3 Tipos de Modelo

É importante saber diferenciar os modelos devido ao método de resolução que varia para cada um deles.

#### 1.3.1 Modelo Linear × Não-linear

Modelos lineares possuem como função objetivo uma função linear e todas as restrições também são lineares. Exemplos:

- $\bullet$  f(x) = ax + b.
- $f(x_1, x_2) = x_1 + x_2 5$ .

Já os não-lineares não obedecem essa regra, podendo ter suas variáveis se multiplicando ou funções trigonométricas e logarítmicas. Exemplos:

- $f(x_1, x_2) = x_1^2 + x_2^2$ .
- $f(x_1, x_2) = \tan(x_1 + x_2)$ .

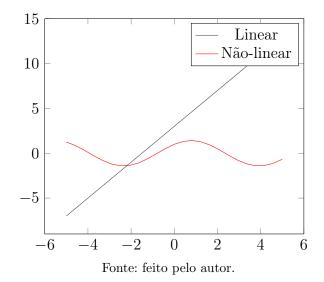

Figura 2 – Exemplo de modelo linear e não-linear.

#### 1.3.2 Modelo Contínuo × Discreto

Um modelo é contínuo quando sua região factível é contínua, ou seja, dado um ponto dessa região todos os seus vizinhos também serão uma solução. Modelos discretos não possuem seu domínio contínuo. A Figura 3 mostra um gráfico com exemplos de um modelo contínuo e outro discreto.

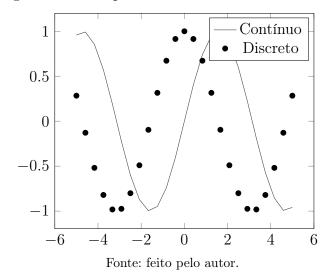

Figura 3 – Exemplo de modelo contínuo e discreto.

#### 1.3.3 Modelo Determinístico × Estocástico

Em modelos determinísticos seus dados são conhecidos, enquanto os estocásticos possuem uma incerteza quanto aos dados.

#### 1.3.4 Tipos de Programação

Com base nas categorias de modelo é possível também dividir métodos de programação (planejamento) para sua solução. HILLIER traz alguns exemplos algoritmos de para os tipos de programação.

- Linear: modelo linear contínuo determinístico. Algoritmos importantes para essa classe de problemas são: o algoritmo Simplex e algoritmos de pontos interiores.
- Inteira: modelo linear discreto determinístico. Aqui se destacam os algoritmos branch-and-bound e branch-and-cut.
- Estocástica: modelo linear contínuo estocástico. Alguns métodos para solução podem se basear em simulação dos eventos aleatórios envolvidos.
- Não-linear: modelo não-linear contínuo determinístico. Os algoritmos para solução de problemas não lineares podem ser baseados em gradiente, mas com frequência dependem bastante do problema a ser resolvido.

#### 1.4 Métodos Exatos × Heurísticos

Métodos exatos sempre vão garantir a solução ótima para o problema, porém encontrar tal solução pode requerer grande tempo e/ou muitos recursos computacionais. Já heurísticas buscam por soluções factíveis e são geralmente usadas em problemas de grande porte.

Um dos métodos exatos mais conhecidos é o algoritmo branch-and-bound, ele realiza a enumeração implícita das soluções viáveis de um problema de programação linear inteira mista, mantendo valores para os limitantes inferior e superior de um problema de otimização. O algoritmo termina sua execução quando ambos os limitantes se igualam, garantindo a otimalidade da solução. Detalhes algoritmo branch-and-bound e outros problemas de programação inteira, como branch-and-cut e planos de corte podem ser vistos no trabalho de WOLSEY.

Como o problema de interesse é NP-difícil e o principal interesse é em instâncias de médio e grande porte, utilizar um método exato seria bastante desafiador e, provavelmente, não seria possível obter um resultado em tempo hábil devido aos recursos computacionais disponíveis. Portanto, métodos heurísticos serão usados, já que eles tendem a diminuir a demanda computacional, porém não garantem otimalidade da solução resultante.

Soluções heurísticas tipicamente alternam entre explorar o espaço de busca de forma mais ampla e se concentrar em uma vizinhança de uma solução viável já encontrada. Por isso, em geral, uma heurística garante apenas a otimalidade local da solução. Para escapar de ótimos locais e buscar atingir um resultado melhor, mecanismos de fuga são usados.

Alguns exemplos desses mecanismos são o multi-start e o simulated annealing (FIRAT; ALPASLAN, 2020; RAKOTONIRAINY; VUUREN, 2020; HOPPER; TURTON, 2001).

Continuando o exemplo do problema da mochila (seção 1.1), uma heurística possível para ele é ordenar os itens de maneira decrescente de acordo com  $\frac{v_i}{w_i}$  e colocá-los na mochila enquanto couber.

As heurísticas podem ser divididas entre heurísticas construtivas e heurísticas de melhoria. Heurísticas construtivas, como diz o nome, constroem uma solução para o problema, enquanto heurísticas de melhoria, partem de uma solução viável e realizam tentativas de melhorar tal solução (MICHALEWICZ; FOGEL, 2013). A heurística bottom-left (detalhada no Capítulo 3), a qual será usada para resolver o problema de empacotamento de retângulos (Capítulo 2), é uma heurística construtiva.

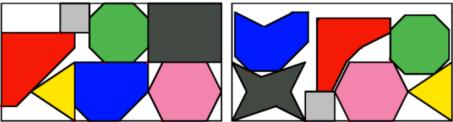

# Problema de Empacotamento

Nas últimas três décadas, as publicações na área de corte e empacotamento tiveram um aumento considerável. Devido a isso, a categorização e organização desses problemas é cada vez mais importante. O trabalho de WÄSCHER et al. fornece a classificação de problemas de corte e empacotamento baseado na sua dimensão, tipos de itens, tipo de recipiente e função objetivo, fornecendo uma atualização da tipologia definida em (DYCKHOFF, 1990).

O problema de empacotamento, é um problema de otimização de difícil resolução. Seu objetivo é simples, colocar peças em um espaço N-dimensional, na Figura 1 é possível ver representações para os casos 1D, 2D e 3D. Tanto as peças quanto o espaço, podem ser de formato regular (convexo) ou não (côncavo). Pensando no caso 2D, triângulos, retângulos, círculos e outros polígonos convexos são considerados regulares, enquanto estrelas e outros polígonos côncavos são irregulares.

Existem diversas formas de identificar se um polígono é convexo ou não. A primeira delas é verificando se existe alguma diagonal que não pertença à região interna do polígono, caso exista, o polígono é côncavo, caso contrário, convexo. Também é possível identificar através dos ângulos internos, polígonos côncavos possuem pelo menos um ângulo interno com mais de 180 graus. Outra forma de definir se uma peça é regular ou não, é o número de parâmetros necessários para representá-la. Se for preciso três ou mais é irregular, caso contrário, regular (BARTMEYER et al., 2021). A Figura 4 mostra alguns exemplos de peças regulares (à direita) e seus contornos convexos (à esquerda).

Figura 4 – Exemplos de peças regulares e irregulares.

Fonte: (BARTMEYER et al., 2021).

O foco deste trabalho será em problemas de empacotamento 2D de peças e objetos retangulares ortogonais, sem qualquer variante (seção 2.3). Por mais simples que seja, é uma categoria muito importante do problema, visto que, no mundo real, a maioria do que temos interesse em resolver se encaixa nessas características. Inclusive, existem vários trabalhos como (WEI et al., 2011) e outros mais recentes (MARTIN et al., 2020; FIRAT; ALPASLAN, 2020; CHEN et al., 2019) com o mesmo propósito. Existem até mesmo

instâncias padronizadas para realizar comparativos entre algoritmos (IORI; LIMA et al., 2022), as instâncias usadas neste trabalho serão explicadas no Capítulo 4.

Tratar somente de objetos retangulares não é um grande limitador para resolver com outros tipos de itens, já que é possível usar os contornos convexos de um polígono côncavo para transformá-lo em um polígono convexo. Após isso, basta transformar o polígono regular em um retângulo. Assim é possível empacotar qualquer polígono usando o empacotamento de retângulos, ainda que haja uma área desperdiçada devido às transformações.

# 2.1 Definição

Com o escopo do estudo definido como problema de empacotamento de retângulos, é possível ver sua definição formal. De acordo com (IORI; LIMA et al., 2022), dado uma caixa retangular  $\mathcal{B} = (W, H)$  de comprimento  $W \in \mathbb{Z}_+$  e altura  $H \in \mathbb{Z}_+$  e um conjunto  $\mathcal{I}$  de itens também retangulares, onde cada item  $i \in \mathcal{I}$  com comprimento  $w_i \in \mathbb{Z}_+, w_i \leq W$  e altura  $h_i \in \mathbb{Z}_+, h_i \leq H$ . Um empacotamento  $\mathcal{I}' \subseteq \mathcal{I}$  em  $\mathcal{B}$  pode ser descrito como uma função  $\mathcal{F} : \mathcal{I}' \to \mathbb{Z}_+^2$  que mapeie cada item  $i \in \mathcal{I}'$  para um par de coordenadas  $\mathcal{F}(i) = (x_i, y_i)$ , de forma:

$$x_i \in \{0, \dots, W - w_i\}, y_i \in \{0, \dots, H - h_i\} (i \in \mathcal{I}')$$
 (1)

$$[x_i, x_i + w_i) \cap [x_j, x_j + w_j) = \emptyset \text{ ou } [y_i, y_i + h_i) \cap [y_j, y_j + h_j) = \emptyset (i, j \in \mathcal{I}', i \neq j)$$
 (2)

Nessa modo de representação a caixa está posicionada no plano cartesiano, com seu canto inferior esquerdo na origem. Já as coordenadas  $\mathcal{F}(i) = (x_i, y_i)$  representam a posição em que o canto inferior esquerdo da peça será alocado. A Restrição 1 garante que cada item deve estar inteiramente na caixa, enquanto a Restrição 2 impede sobreposição entre peças. Ambas restrições indicam uma orientação fixa, ou seja, peças não podem ser rotacionadas, mas elas podem ser adaptadas para considerar essa variante (seção 2.3).

# 2.2 Classificação

Por existirem diferentes objetivos na solução de um problema de empacotamento foram criadas algumas classificações. Algumas delas (as principais) são mostradas em (IORI; DE LIMA et al., 2021; IORI; LIMA et al., 2022), as quais serão exploradas em seguida, com alguns exemplos já vistos na Introdução.

O objetivo do **Empacotamento 2D em Faixa**, em inglês *Two-Dimensional Strip Packing Problem* (2D-SPP), é encontrar um empacotamento de altura mínima H para um dado conjunto de itens  $\mathcal{I}$  em uma caixa  $\mathcal{B} = (W, H)$  com comprimento fixo W. Muito

aplicado na área têxtil para minimizar o comprimento de tecido cortado para fazer peças de roupas.

No Empacotamento 2D da Mochila, em inglês Two-Dimensional Knapsack Pro-blem (2D-KP), dado um conjunto de itens  $\mathcal{I}$ , onde cada item  $i \in \mathcal{I}$  é associado a um valor  $p_i$ , e uma caixa  $\mathcal{B}$ , deve-se encontrar um subconjunto  $\mathcal{I}' \subseteq \mathcal{I}$  que maximize  $\sum_{i \in \mathcal{I}'} p_i$ . Geralmente o valor  $p_i$  é dado pela área do item, dessa forma, outra interpretação do problema seria minimizar a área desperdiçada (vazia) da caixa  $\mathcal{B}$ . Pode ser utilizado para maximizar o número de peças cortadas de um pedaço de couro, por exemplo.

Já o Empacotamento 2D em Caixas, em inglês Two-Dimensional Cutting Stock Problem (2D-CSP), envolve encontrar uma solução que minimize o número de caixas idênticas necessárias para empacotar todos os itens  $i \in \mathcal{I}$ , onde cada item possui uma demanda  $d_i \in \mathbb{Z}_+$  (número mínimo de cópias do item que precisam ser empacotadas). Existe uma versão menos genérica do 2D-CSP, o Two-Dimensional Bin Packing Problem (2D-BPP), onde a demanda  $d_i$  de cada item é 1. As caixas podem possuir diferentes tamanhos ao utilizar uma variante (seção 2.3), mas a maioria dos problemas lida com as mesmas dimensões. Facilmente aplicável na área logística e de transporte, seja minimizando o número de paletes ou veículos de entrega.

Por fim, no **Empacotamento 2D Ortogonal**, em inglês *Two-Dimensional Ortho*gonal Packing Problem (2D-OPP), busca-se uma solução, caso exista, para empacotar **todos** os itens  $i \in \mathcal{I}$  na caixa  $\mathcal{B}$ . Usado em situações onde se precisa alocar todos os itens dentro de um caminhão.

Todos os problemas descritos são NP-difícil, com exceção do Ortogonal, sendo NP-completo (IORI; LIMA et al., 2022). Resultados recentes para as classes do problema podem ser vistos em (CÔTÉ et al., 2014; DELORME et al., 2017; VELASCO; UCHOA, 2019; MARTIN et al., 2020; MRAD, 2015; CINTRA et al., 2008; FURINI et al., 2016). A Figura 5 traz exemplos de solução ótima para 2D-SPP, 2D-BPP e 2D-KP, para um dado conjunto de itens.

Este trabalho resolverá as instâncias de teste somente para o 2D-KP, onde o valor  $p_i$  de cada item i será sua própria área, independente do valor original da instância (caso tenha).

### 2.3 Variantes

Variantes são pequenas alterações no escopo do problema, também podem ser vistas como restrições ou relaxamento. Existem quatro mais comuns (IORI; LIMA et al., 2022), as quais são descritas a seguir.

Corte guilhotinado consiste em cortar a caixa de forma paralela a um de seus lados recursivamente, é útil na resolução de problemas de corte (problemas de empacotamento podem ser reduzidos para essa categoria e vice-versa). Rotações ortogonais são um

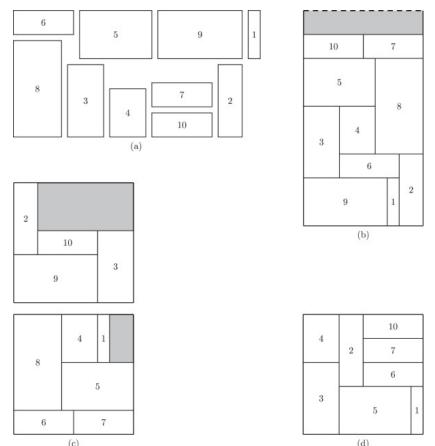

Figura 5 – Exemplo de solução ótima para algumas classes.

(a) conjunto de itens; (b) solução ótima para 2D-SPP; (c) solução ótima para 2D-BPP;

(d) solução ótima para 2D-KP (se os valores dos itens corresponderem a sua área).

Fonte: (IORI; DE LIMA et al., 2021).

modo de relaxar o problema, permitindo rotações de 90 graus para os itens a serem alocados.

Restrições de carga e descarga implicam que algumas peças devem ser posicionadas em dada posição, usando como exemplo um caminhão de entregas, visa evitar situações onde um produto precisa ser descarregado para se ter acesso a um item mais ao fundo e então carregar novamente o primeiro item. Existem variantes aplicáveis somente a algumas categorias do problema, é o caso de caixas de tamanho variável que pode ser unida ao Empacotamento 2D em Caixas e define que caixas não têm de ter as mesmas dimensões.

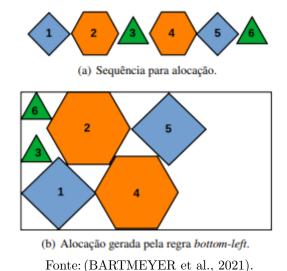

# 3 Métodos de solução

Como descrito na seção 2.2, a maioria das classes do problema são NP-difíceis. Isso torna métodos de soluções exatos, os quais buscam pela solução ótima, extremamente custosos em tempo e recursos computacionais em instâncias de porte moderado, muitas vezes sendo inviáveis por falta de algum desses dois motivos. Consequentemente a literatura é dominada por abordagens que usam heurísticas e meta-heurísticas, sendo a bottom-left uma das principais estratégias de solução e será usada no estudo deste trabalho.

A bottom-left é uma heurística construtiva (seção 1.4) proposta por BAKER et al. em 1980. Embora tenha sido proposta a décadas, ela ainda é bastante usada na literatura atual, além de poder ser usada como componente de algoritmos mais sofisticados e para diferentes classes e variantes do problema. Ela foi utilizada nos trabalhos de HOPPER; TURTON na comparação de vários métodos de solução, WEI et al. trazendo uma revisão do método e seus derivados e, mais recentemente, CHEHRAZAD et al. através de uma adaptação para o empacotamento de itens irregulares de forma gulosa.

Sua premissa é simples, dado uma fila de itens como entrada, enquanto ela não estiver vazia, basta retirar o primeiro item dela e alocar no canto mais a baixo e à esquerda quanto for possível (BARTMEYER et al., 2021), sem sobreposições entre peças (seção 2.1). Caso não exista uma posição válida, a peça é desconsiderada e passa-se para próxima da fila. A Figura 6 mostra um exemplo de alocação para um dado conjunto de peças regulares.

Figura 6 – Representação de alocação usando bottom-left.

Vale destacar que a própria ordem da fila pode gerar resultados diferentes, alterando a qualidade da solução. Um dos resultados esperados deste trabalho é identificar se há alguma forma de ordenação que se destaque na qualidade de solução, através da comparação

entre os diferentes modos. Para isso, serão usados conjuntos de instâncias frequentemente utilizados na literatura.

## 3.1 Critérios de ordenação

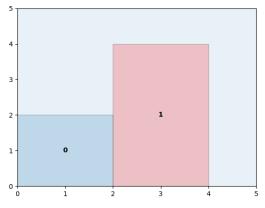

Para determinar o impacto da ordenação da fila, cinco critérios de ordenação foram escolhidos, sendo eles: área, perímetro, largura, altura e *id*. A ordenação por *id* considera a ordem em que os itens foram colocados na lista, ou seja, seria a forma padrão de resolver e ele será a base para definir se os demais critérios possuem algum benefício. Além disso, cada critério pode ser usado para ordenar a fila em ordem crescente ou decrescente, algo que também será analisado. Na literatura o mais comum é utilizar a ordenação decrescente pela área (CHEN et al., 2019).

# 3.2 Sobreposição e domínio contínuo

Por mais simples que a heurística bottom-left seja, ainda existem dois desafios, respeitar a Restrição 2 (sobreposição de peças) e o domínio contínuo de coordenadas ao tentar alocar um item. As Figuras 7 a 11 serão usadas para demonstrar os desafios citados.

Supondo uma instância com recipiente de altura e largura 5 e três itens retangulares a serem alocados, nesta ordem, com as seguintes dimensões: altura e largura 2, altura 4 e largura 2 e altura 1 e largura 3. A Figura 7 mostra o estado intermediário do algoritmo de solução, onde o item 0 foi alocado na coordenada (0, 0) e o item 1 foi alocado a sua direita na posição (2, 0) para respeitar a Restrição 1, porque não cabe logo acima na posição (0, 2).

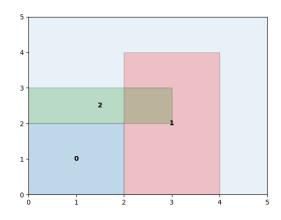

Fonte: feito pelo autor.

Como a próxima peça da fila tem largura 3 e altura 1, ao posicioná-la na posição (0, 2) percebe-se que a Restrição 1 é satisfeita, mas a Restrição 2 não (Figura 8).

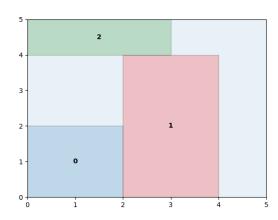

Figura 8 – Itens 0, 1 e 2 posicionados, mas com sobreposição.

Fonte: feito pelo autor.

Nesse caso, com poucas peças alocadas e auxílio visual, é fácil identificar que a posição correta, seguindo a lógica bottom-left, seria a de coordenadas (0, 4) (Figura 9). Porém, encontrar tal posição pode ser extremamente complexo. Entre as coordenadas (0, 2) e (0, 4) o espaço é contínuo, existindo infinitas outras coordenadas entre elas, sendo impossível checar todas.

Figura 9 – Itens 0, 1 e 2 posicionados, sem sobreposição.

Fonte: feito pelo autor.

Como todas as instâncias usadas para testes tratam somente de peças e recipientes com valores inteiros, uma abordagem possível seria discretizar o domínio, conforme a Figura 10.

3

Figura 10 – Itens 0 e 1 posicionados, com domínio discreto.

Fonte: feito pelo autor.

Dessa forma somente coordenadas de valores inteiros precisariam ser verificadas, resolvendo parcialmente o problema com o domínio, já que ainda existiriam muitos pontos, principalmente em instâncias com recipientes grandes. Mas isso ainda não resolve a parte de sobreposição. Para cada ponto ainda é necessário verificar se existe sobreposição com cada uma das peças já alocadas, algo custoso.

Na Figura 11 é possível notar que três coordenadas precisaram ser checadas até encontrar uma que cumprisse as Restrições 1 e 2. Por se tratar de um estado inicial de uma instância pequena esse processo não é tão custoso, porém em instâncias maiores ou estados mais avançados isso se tornará cada vez mais custoso, visto que o domínio será maior e, principalmente, mais peças estarão alocadas para checar possíveis sobreposições.

Fonte: feito pelo autor.

Outro fator o qual deve ser observado é de que a discretização do domínio pode não funcionar bem em casos onde os valores trabalhados não sejam inteiros. Nesses casos a discretização poderia ocorrer com algum nível de precisão nas casas decimais, mas ainda

assim as chances de desperdício de área são grandes. Ou seja, muitos problemas reais seriam complexos de serem resolvidos com a discretização.

# 3.3 Criação de regiões

Os dois problemas expostos na seção 3.2 podem ser resolvidos utilizando a estratégia de criação de regiões. Com essa técnica, a Restrição 2 é trivialmente satisfeita. Nela, ao posicionar uma peça, duas regiões são criadas e o item seguinte será somente posicionado se couber em uma das regiões disponíveis.

Supondo um recipiente com altura e largura 40 e um item 0 com altura 4 e largura 7. Quando o item for posicionado na coordenada (0, 0), duas regiões, R1 e R2, serão criadas (Figura 12). A região R1 começará na coordenada (0, 4) e a R2 na (7, 0).

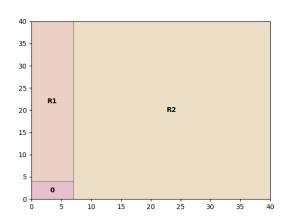

Figura 12 – Regiões criadas traçando uma linha vertical.

Fonte: feito pelo autor.

Agora o domínio passa a ser somente o canto inferior esquerdo de cada uma das regiões e sobreposições deixam de ser possíveis. Além disso, a regra para definir se uma peça cabe em dada região é igual a Restrição 1, tornando o algoritmo de solução bem simples. A fim de identificar o impacto das regiões na solução do modelo, quatro formas de criação delas foram usadas.

A primeira delas é **traçando uma linha vertical** a partir do canto superior direito de cada peça alocada (Figura 12). Nela a região R1 terá altura 36 e largura 7, indo até à coordenada (7, 40). Enquanto a R2 possuirá altura 40 e largura 33, chegando até à coordenada (40, 40).

A segunda é semelhante à primeira, porém **traçando uma linha horizontal** (Figura 13). Nesse caso, R1 terá altura 36 e largura 40, indo até à coordenada (40, 40). Já R2 possuíra altura 4 e largura 33, chegando até à coordenada (40, 4).

40 35 -30 -25 -20 -15 -10 -5 -

Figura 13 – Regiões criadas traçando uma linha horizontal.

Fonte: feito pelo autor.

10

15

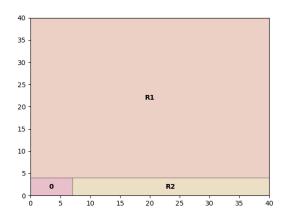

R2

25

30

Na terceira, a linha traçada (vertical ou horizontal) depende da área das regiões criadas com cada linha. Nesse modo o objetivo é maximizar a área de uma das regiões geradas, ele **identifica qual linha irá gerar a região de maior área e a traça**. Por exemplo, a Figura 12 gerou uma região com 252 de área e outra com 1320, enquanto a Figura 13 obteve regiões com 1440 e 132, então, nesse caso, a linha traçada será a horizontal (Figura 14).

Figura 14 – Regiões criadas maximizando uma das regiões.

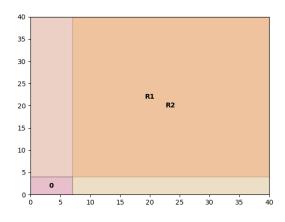

Fonte: feito pelo autor.

Maximizar uma região pode ser interessante, pois aumenta as chances do próximo item conseguir ser alocado, visto que uma das regiões será mais espaçosa. Em contrapartida, esse método também pode acabar gerando muitas regiões pequenas que não sejam utilizadas, diminuindo a qualidade da solução.

No quarto e último modo de criar regiões nenhuma linha é traçada, todas as regiões vão até o final do recipiente (Figura 15), criando **regiões sobrepostas**. R1 terá altura 40 e largura 36, enquanto R2 possuirá altura 40 e largura 33. Então, R1 e R2 terminarão na

coordenada (40, 40). Nesse caso, sobreposições de peças podem ocorrer, então verificações são necessária para cumprir a Restrição 2. Ao fazer isso, é possível que mais peças sejam alocadas, visto que todas as regiões possuem área máxima. Esse modo foi criado para identificar se é de fato melhor que os demais e qual seu custo.

Figura 15 – Regiões criadas possibilitando sobreposições.

Fonte: feito pelo autor.

Com os critérios para criação de regiões explicados, é possível diferenciá-los em dois tipos. O primeiro é dos que permitem sobreposição entre peças e, por isso, precisam de verificações para respeitar a Restrição 2 (regiões complexas), nesse tipo se encaixa somente o quarto modo. O segundo tipo contém os três primeiros critérios, onde somente a Restrição 1 precisa ser checada (regiões simples).

A Tabela 1 mostra, de forma resumida, os quatro modos de criar regiões, seu tipo (regiões simples ou complexas) e sua relação com a Restrição 2. A coluna "Divisão" indica o critério usado ao criar as regiões, enquanto a coluna "Restrição 2" mostra se a Restrição 2 é trivialmente satisfeita ou não.

Tabela 1 – Modos de criar regiões, seu tipo e sua relação com a Restrição 2.

Modo	Divisão	Restrição 2	Tipo
1	Vertical	Trivial	Simples
2	Horizontal	Trivial	Simples
3	Maior área	Trivial	Simples
4	Regiões sobrepostas	Não trivial	Complexas

# 4 Resultados

Para testar os métodos de solução criados foram usadas 45 instâncias de teste da literatura, separadas em cinco conjuntos de instância de características diferentes: BKW, GCUT, NGCUT, OF e OKP. Todas as elas foram obtidas através da biblioteca pública 2DPackLib<sup>1</sup> (IORI; LIMA et al., 2022).

O foco do trabalho é no 2D-KP e com o critério de maximização sendo a área ocupada do espaço. Mas nem todos conjuntos foram feitos para ser resolvidos dessa forma, nesses casos foram feitas leves adaptações para usá-los. O motivo de usar instâncias feitas com outro objetivo é para não viciar o modelo em instâncias específicas.

As instâncias BKW foram propostas para 2D-SPP (BURKE et al., 2004), esse conjunto é interessante, pois existe uma solução ótima onde todos os itens podem ser alocados. CÔTÉ et al. apresentam alguns resultados para esse conjunto, já DELORME et al. trazem resultados usando rotações ortogonais.

Instâncias GCUT foram propostas para 2D-KP com corte guilhotinados (BEASLEY, 1985a). Esse conjunto já foi usado na literatura no 2D-SPP (CÔTÉ et al., 2014), 2D-SPP com corte guilhotinado (MRAD, 2015), 2D-SPP com rotações ortogonais (DELORME et al., 2017) e 2D-CSP com corte guilhotinado (CINTRA et al., 2008).

NGCUT é um conjunto proposto para 2D-KP (BEASLEY, 1985b). Ele possui resultados recentes para 2D-KP, 2D-SPP (CÔTÉ et al., 2014) e 2D-SPP com rotações ortogonais (DELORME et al., 2017).

As instâncias OF foram inicialmente elaboradas para 2D-KP com cortes guilhotinados (OLIVEIRA; FERREIRA, 1990) e foram resolvidas recentemente com o mesmo propósito (VELASCO; UCHOA, 2019; MARTIN et al., 2020).

Por fim, instâncias OKP foram criadas para 2D-KP (FEKETE; SCHEPERS, 1997) e já foram resolvidas para versões sem e com corte guilhotinado (FURINI et al., 2016).

Como são cinco critérios de ordenação (seção 3.1), com cada critério podendo ser crescente ou decrescente, quatro formas de criar regiões (seção 3.3) e 45 instâncias, temse o total de 1800 casos de teste. Além disso, para conseguir resultados mais fiéis, a média, mediana e desvio padrão foram calculados. Por isso, cada caso foi executado cinco vezes, totalizando 9000 execuções. Outros dados como a qualidade de solução (objetivo do trabalho), média de itens alocados e tempo, também foram computados. Todas as execuções foram feitas em um mesmo computador, com configurações conforme a Tabela 2.

Ao analisar a média, a mediana e o desvio padrão, observou-se que a média e mediana possuem valores quase idênticos, enquanto o desvio padrão é pequeno ao ponto de poder

Disponível em: https://site.unibo.it/operations-research/en/research/2dpacklib. Acessado em: 10 de junho de 2023.

Tabela 2 – Configuração do computador de testes.

CPU	AMD Ryzen <sup>TM</sup> 5 3600X
RAM	16 GiB
Python	3.11.0
SO	Linux Mint 21.1 Cinnamon
Kernel	5.15

ser ignorado, indicando que cinco execuções por caso de teste são suficientes. Portanto, a mediana e desvio padrão serão omitidos no restante do trabalho, podendo ser encontrados na versão completa dos dados gerados no Github<sup>2</sup>. No Apêndice A é possível ver uma versão resumida de todos os dados gerados (sem mediana e desvio padrão).

# 4.1 Ordenação crescente × decrescente

A primeira coisa a qual fica evidente com os resultados é a discrepância na qualidade de solução entre a ordenação crescente e a decrescente, algo já esperado. Na Tabela 3 é possível notar que ordenando de forma decrescente é possível ocupar cerca de 20% a mais do espaço (coluna "Qualidade %"), quando comparado a ordenação crescente.

Tabela 3 – Resultado da comparação entre Desc..

Desc.	Wons	Draws	Quality %	Items %	Time (s)
T	736	8	78.9136	46.3642	1.7798e+00
F	167	8	57.3060	47.6518	2.3715e+00

Fonte: autor

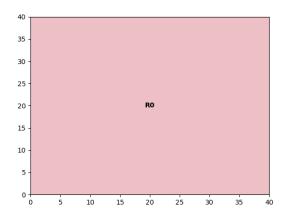

A coluna "Vitórias" indica quantas vezes tal método de solução obteve o melhor resultado em comparação com os demais métodos em outras linhas. Enquanto a coluna "Empates" mostra a quantidade de vezes que o método conseguiu a melhor qualidade, mas outros também conseguiram. Essas colunas foram feitas da seguinte forma: entre cada combinação de critério de ordenação, modo de criar regiões e instâncias, é feita a comparação se a qualidade de solução foi melhor para ordenação crescente ou decrescente. No caso de ambas conseguirem o melhor resultado, é acrescido 1 tanto na coluna "Vitórias", quanto na "Empates" de ambas. Por fim, a coluna "Tempo (s)" mostra o tempo médio de execução do método em segundos.

Com isso, fica claro que ordenar a fila de entrada da bottom-left de modo decrescente é vantajoso em termos de qualidade, quantidade e tempo de execução. Isso se deve a como as regiões são criadas, as Figuras 16 a 19 serão utilizadas para exemplificar, elas representam estados do modelo usando ordenação crescente pela altura e linhas horizontais

Disponível em: https://github.com/G-Carneiro/packing-problem/. Acessado em: 10 de junho de 2023.

para criação de regiões para a instância BKW01. A Figura 16 representa o estado inicial do algoritmo de solução, onde ainda não existem peças alocadas.

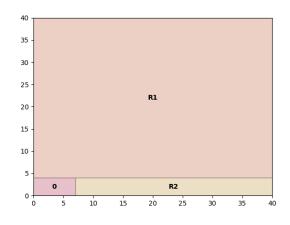

Figura 16 – Regiões criadas na ordenação crescente - estado inicial.

Fonte: feito pelo autor.

Ao posicionar uma peça, uma das regiões ficará com a mesma altura do item recémposicionado (Figura 17), como a ordenação é crescente a próxima peça terá no mínimo a mesma altura, mas o provável é que seja mais alta, impossibilitando seu posicionamento nessa região.

Figura 17 – Regiões criadas na ordenação crescente - estado 1.

Fonte: feito pelo autor.

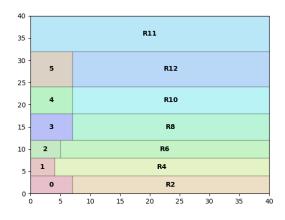

O mesmo irá ocorrer para todos os itens seguintes (Figura 18), fazendo com que muitas regiões fiquem sem poder receber peças.

Figura 18 – Regiões criadas na ordenação crescente - estado 2.

Fonte: feito pelo autor.

A Figura 19 mostra o estado final do algoritmo de solução e grande parte do espaço ainda está livre. Na Tabela 11 do Apêndice A é possível ver que a qualidade de solução do modelo com essas combinações foi de 12.75%, enquanto ao utilizar ordenação decrescente foi possível encontrar uma solução de 100%. Algo semelhante ocorre com outros critérios de ordenação e criação de regiões.

Figura 19 – Regiões criadas na ordenação crescente - estado final.

# 4.2 Comparativo entre critérios de ordenação

Ao comparar os diferentes critérios de ordenação (Tabela 4), inicialmente algo parece errado, a ordenação por *id* (nenhuma ordenação) está com os melhores resultados qualitativos. Além disso, todos os critérios conseguiram praticamente a mesma qualidade média.

OD 1 1 4	T) 1, 1	1	~	4	• • • •	1	1 ~
Tabela 4 –	Resultado	da	comparação	entre	criterios	de	ordenacao
Tabela I	resultado	aa	COMPARAÇÃO	CITUIC	CITUCITOD	ac	or acmação.

Ordenação	Wons	Draws	Quality %	Items %	Time (s)
A	81	56	67.7915	46.2000	2.0726e+00
P	93	52	68.9870	46.1442	2.0366e+00
H	73	24	65.9848	45.7611	1.8254e+00
W	94	32	69.1286	48.0083	2.3444e+00
I	127	12	68.6572	48.9263	2.0995e+00

Fonte: autor

Como mencionado anteriormente (seção 4.1), ordenar a fila de forma crescente gera resultados ruins. Mas isso não ocorre quando o critério de ordenação é o *id*, porque nele tem-se peças sem seguirem alguma ordem. Com esse critério o impacto da escolha entre ordenação crescente ou decrescente é praticamente nulo. Por isso ele também se saí muito melhor que os demais na ordenação crescente, sendo o vitorioso na esmagadora maioria. Já as qualidades próximas se justificam nos critérios diferentes do *id* pois a discrepância entre ordenação crescente e decrescente é muito grande, mas ao tirar média isso acaba não ficando evidente.

A Tabela 5 mostra o mesmo comparativo que a Tabela 4, porém agora somente considerando a ordenação decrescente, já que não existem motivos para usar a crescente. Representando os dados dessa forma fica fácil identificar que utilizar algum critério de ordenação para a fila de entrada é vantajoso, pois ao usar o *id* os resultados foram os piores. Além disso, percebe-se que as ordenações por área e perímetro obtiveram os melhores resultados, ainda que os demais também sejam competitivos.

Tabela 5 – Resultado da comparação entre critérios de ordenação decrescente.

Ordenação	Wons	Draws	Quality %	Items %	Time (s)
A	63	39	82.7353	44.0979	1.5874e+00
P	71	38	84.6986	44.8012	1.5769e+00
H	40	16	77.4182	46.3004	1.5655e+00
W	66	24	81.1899	47.6751	2.0805e+00
I	16	5	68.5261	48.9461	2.0889e+00

Fonte: autor

A alta competitividade entre os critérios de ordenação é interessante, pois a maioria dos trabalhos na literatura, como o de CHEN et al., usam somente ordenação pela área, e isso pode ser um forte indicativo que os demais critérios devem ser mais explorados em certas circunstâncias. Ao considerar somente a ordenação decrescente deixa claro que a alta quantidade vitórias do critério *id* na Tabela 4 realmente se deve a ordenação crescente.

# 4.3 Comparativo entre criação de regiões

O comparativo entre métodos de criação de regiões gerou resultados interessantes, na Tabela 6 ocorre algo semelhante ao da Tabela 4. Regiões criadas de modo a ser necessário verificar sobreposições obtiveram excelentes resultados qualitativos (última linha), pois são pouco afetadas pela ordenação crescente (seção 4.1), assim como o critério de ordenação por id, já que as regiões sempre possuem área máxima (seção 3.3).

Tabela 6 – Resultado da comparação entre criação de regiões.

Região	Wons	Draws	Quality %	Items %	Time (s)
V	155	102	65.0025	45.6288	2.4311e-03
H	122	101	63.0163	44.1025	7.2323e-03
М	189	158	69.5409	48.7214	1.3313e-02
N	334	195	75.0333	49.6378	8.4208e+00

Fonte: autor

Ao considerar somente a ordenação decrescente (Tabela 5), a diferença em relação aos demais métodos de criação diminui, ainda que o último modo permaneça sendo o melhor qualitativa e quantitativamente. Os modos criados traçando uma linha vertical ou horizontal apresentaram qualidades semelhantes e os menores tempos de execução, mas o método o qual traça uma linha vertical obteve mais vitórias. Regiões criadas para maximizar uma das mesmas conseguiram o segundo melhor resultado qualitativo e quantitativo, ao custo de um pequeno acréscimo no tempo de execução em relação aos dois primeiros. O último modo de fato conseguiu os melhores resultados, porém a um custo altíssimo, levando cerca de 1000 vezes mais tempo que métodos mais rápidos.

Tabela 7 – Resultado da comparação entre criação de regiões - ordenação decrescente.

Região	Wons	Draws	Quality %	Items %	Time (s)
V	98	79	76.4030	45.0191	2.7157e-03
H	70	60	75.9970	45.5439	6.2101e-03
M	104	89	79.7175	47.6795	1.3743e-02
N	176	119	83.6420	47.2335	7.2176e+00

Fonte: autor

A Tabela 8 traz um comparativo entre os dois tipos de criação de regiões, os que é preciso checar sobreposição e os que não (seção 3.3). Na primeira linha da tabela a coluna "Qualidade %" representa a média do melhor resultado obtido em cada instância e a coluna "Tempo Total (s)" mostra a soma dos tempos que cada método de solução levou para cada instância. As duas colunas consideram somente métodos de solução que usam regiões onde não são necessárias verificações de sobreposição, ou seja, são considerados 30 modos de solução. A segunda linha considera somente método de solução o qual utiliza ordenação decrescente pela área e criação de regiões onde é necessário verificar sobreposições, esse método foi escolhido para o comparativo por apresentar os melhores resultados quantitativos e ser o segundo melhor qualitativamente (seção 4.4).

Tabela 8 – Resultado da comparação entre tipos de regiões.

Superposição	Qualidade %	Tempo Total (s)
Não	90.8278	1.6299e+01
Sim	87.2957	2.8313e+02

Fonte: autor

Com a Tabela 8 fica claro que, por mais que usar regiões onde é preciso checar sobreposições apresente o melhor resultado, é melhor executar todos demais métodos os quais não precisem e escolher somente o de melhor solução, pois assim é possível obter, na média, soluções de maior qualidade e ainda levando 10 vezes menos tempo.

# 4.4 Comparativo entre combinações

A Tabela 9 contém os resultados para cada um dos quarenta métodos de solução feitos. Com ela é possível identificar qual dos métodos apresenta melhores resultados qualitativos e quantitativos.

Dentre os métodos que usam regiões onde é preciso checar sobreposições, os mais interessantes são o de ordenação decrescente pela área (linha 30), pelo perímetro (linha 32) e pela largura (linha 36). Utilizando a área conseguiu-se o segundo melhor resultado quantitativo e também qualitativo. Com o perímetro foi possível atingir o terceiro maior número de vitórias e a melhor qualidade de solução. Por fim, a largura obteve o melhor resultado quantitativo e ficou em terceiro na qualidade de solução.

Nos métodos que usam regiões mais simples, os resultados foram bem variados nas combinações, dentre eles se destacam: regiões criadas usando linha vertical e ordenação pela largura (linha 6) e maximizar uma região e ordenar pela área (linha 20) ou pelo perímetro (linha 22). O método da linha 6 ficou em terceiro lugar no critério quantitativo (empate com a linha 32) e conseguiu a quinta posição na qualidade de solução. As linhas 20 e 22 tiveram a quarta maior quantidade de vitórias (empate também com a linha 2), já qualitativamente a linha 20 obteve a sexta melhor média nas soluções, enquanto a linha 22 conseguiu a quarta.

Ainda que os resultados dos métodos que usam regiões as quais calculam sobreposições sejam melhores, não compensa utilizá-los, como visto na seção 4.3.

## 4.5 Complexidade

As seções 4.3 e 4.4 deixaram claro que regiões onde a sobreposição pode ocorrer são mais custosas no tempo de execução. Isso acontece devido à complexidade do algoritmo de solução do modelo.

Tabela 9 – Resultado da comparação entre todos os métodos de solução.

Em regiões simples, onde não podem acontecer sobreposições, é necessário verificar se o item a ser alocado cabe em uma região. No pior caso todas as peças só conseguiriam ser alocadas na última região checada. É possível descobrir o número máximo de regiões disponíveis no momento de alocação do item i da fila.

Para o primeiro item, existe somente uma região, o próprio espaço. Após alocar o primeiro item, tem-se duas regiões disponíveis para posicionar o segundo. Ao posicionar uma peça o número de regiões é acrescido em um. Com isso, é possível afirmar que para alocar o item i será preciso verificar no máximo i regiões. Somando o máximo de regiões

para cada item chega-se no número máximo de regiões a serem verificadas no pior caso. Considerando n itens, tem-se a Equação 1.

$$\sum_{i=1}^{n} i \tag{1}$$

Como a soma de 1 até n pode ser reescrita utilizando a Equação 2 (MERCA, 2015), tem-se que o número máximo de regiões a serem verificadas para solucionar o modelo é  $\frac{n^2+n}{2}$ .

$$\sum_{k=1}^{n} k = \frac{n(n+1)}{2} \tag{2}$$

Para regiões complexas, além desse número de regiões, ainda é necessário verificar sobreposições. No pior caso, ao alocar o item i, para cada região será preciso verificar sobreposições com todos os itens i-1 (Equação 3).

$$\sum_{i=1}^{n} i(i-1) \tag{3}$$

Usando a Fórmula de Faulhaber (MERCA, 2015) é possível reescrever a soma dos quadrados dos n primeiros números inteiros como mostra a Equação 4.

$$\sum_{k=1}^{n} k^2 = \frac{n(n+1)(2n+1)}{6} \tag{4}$$

Assim, ao reescrever a Equação 3 utilizando as Equações 2 e 4, tem-se que, no pior caso, será necessário verificar se existe sobreposição entre peças  $\frac{n^3-n}{3}$  vezes. Para n=3152, seriam quase cinco milhões de regiões e mais 10 bilhões de sobreposições a serem checadas, explicando o tempo elevado ao executar um método de solução utilizando regiões complexas.

# 4.6 Conjuntos de instâncias

A Tabela 10 considera os melhores resultados para cada conjunto de instância. As colunas "Qualidade %" e "Itens %" representam, respectivamente, a média percentual da qualidade de solução e itens alocados no melhor resultado de cada instância, considerando apenas os métodos que utilizam regiões simples. Já a coluna "Tempo Total (s)" traz o tempo total, em segundos, de execução para todos os métodos em todas as instâncias do conjunto.

É possível notar que foi possível atingir ótimos resultados em um baixo período. No conjunto BKW, o qual é possível alocar todos os itens, levou mais tempo que os demais, pois possuí a maior quantidade de instâncias e algumas com várias peças. Os conjuntos OF e OKP possuem poucas instâncias e, por isso, tiveram pouco tempo de execução.

Tabela 10 — Resultados para os conjuntos de instância.

Conjunto	Qualidade %	Itens %	Tempo Total (s)
BKW	94.4783	85.7782	1.2688e+01
GCUT	84.6060	20.0994	2.0189e-01
NGCUT	88.2085	35.0307	8.1531e-01
OF	92.0714	34.0580	1.0821e-02
OKP	93.9360	22.8232	1.1026e-01

De forma geral, todos os conjuntos conseguiram uma excelente qualidade média, sendo o GCUT e NGCUT os únicos a ficarem abaixo de 90%.
